

The Python `time` Module

You'll learn to...

- Understand core concepts at the heart of working with dates and times, such as epochs, time zones, and daylight savings time
- Represent time in code using floats, tuples, and `struct_time`
- Convert between different time representations
- Suspend thread execution
- Measure code performance using `perf_counter()`

TABLE OF CONTENTS

- ▶ **1. Dealing with Python time in seconds**
 - 2. Time zones
 - 3. Python time in data structures
 - 4. String representations
 - 5. Python time for performance measurement

The Epoch

An Epoch is a fixed point in time from which other times can then be represented as “distances” from that time. In Windows/UNIX computing, the epoch is January 1st, 1970, at midnight.

Earlier times are negative

A very simple example

TABLE OF CONTENTS

1. Dealing with Python time in seconds
- ▶ **2. Time zones**
3. Python time in data structures
4. String representations
5. Python time for performance measurement

2. Time zones
-  **3. Python time in data structures**
4. String representations
5. Python time for performance measurement

Python time as a tuple

1. Year
2. Month as an integer, ranging between 1 (January) and 12 (December)
3. Day of the month
4. Hour as an integer, ranging between 0 (12 A.M.) and 23 (11 P.M.)
5. Minute
6. Second
7. Day of the week as an integer, ranging between 0 (Monday) and 6 (Sunday)
8. Day of the year
9. Daylight savings time as an integer with the following values:
 - a. 1 is daylight savings time.
 - b. 0 is standard time.
 - c. -1 is unknown.

Conclusion

You've learned...

- About epochs, time zones, and daylight savings time in Python
- How to represent time in code using floats, tuples, and `struct_time`
- How to convert between different time representations
- How the `sleep` function can be used to suspend thread execution
- How to measure code performance using `perf_counter()`
